

Vacuum Cannon Calculations

4.December.2009

Assumptions

These calculations make several (incorrect) assumptions:

1. There is no friction at all (including air resistance) affecting the ping-pong ball.
2. The ping-pong ball undergoes constant (uniform) acceleration.
3. The ping-pong ball's velocity is unaffected by breaking through the tape when exiting the barrel.

Numerical Values

Cannon length: $x = 121 \text{ inches} = 3.07 \text{ meters}$.

Cannon bore diameter: $d_{bore} = 1.6 \text{ inches}$.

Ping-pong ball diameter: $d = 40 \text{ mm} \rightarrow A = \pi(20 \text{ mm})^2 = 1.256 \times 10^3 \text{ mm}^2 = 1.256 \times 10^{-3} \text{ m}^2$.

Ping-pong ball mass: $m = 2.5 \text{ grams} = 2.5 \times 10^{-3} \text{ kg}$.

Atmospheric pressure: $P = 1 \text{ atm} = 14.7 \text{ psi} = 101,325 \text{ N/m}^2$.

Aluminum can mass: $m_{can} = 13.2 \text{ grams}$.

Calculations

Pressure = Force/Area or $F = P \cdot A$:

$$F = P \cdot A = (101,325 \text{ N/m}^2)(1.256 \times 10^{-3} \text{ m}^2) = 127.3 \text{ N}$$

Force = mass · acceleration or $a = F/m$:

$$a = F/m = (127.3 \text{ N}) / (2.5 \times 10^{-3} \text{ kg}) = 5.09 \times 10^4 \text{ m/s}^2 = 5,192 \text{ g}$$

Assuming a constant acceleration a over a distance x , $v_f^2 = v_i^2 + 2ax$, but $v_i = 0$:

$$v_f^2 = 2ax \text{ or } v_f = \sqrt{2ax} = \sqrt{2(5.09 \times 10^4 \text{ m/s}^2)(3.07 \text{ m})} = 559 \text{ m/s} = 1834 \text{ ft/s} \approx \text{Mach } 1.6$$

The kinetic energy of the ping-pong ball is $E = \frac{1}{2}mv^2$:

$$E = \frac{1}{2}mv^2 = \frac{1}{2}(2.5 \times 10^{-3} \text{ kg})(559 \text{ m/s})^2 = 391 \text{ Joules}$$

Notes

For comparison, a .22LR rifle has a typical muzzle energy of 159 Joules and a .38 Special pistol has a typical muzzle energy of 420 Joules (source: http://en.wikipedia.org/wiki/Muzzle_energy). The ping-pong ball isn't going nearly as fast as calculated. These calculations only serve as an exercise.
